

in a warming world:

The latest science
on present-day impacts
and future projections
of sea-level rise

1. The Current State of Sea-Level Rise

**Global-mean sea level is rising
and accelerating as a direct
consequence of human-induced**

The magnitude, timing, and rate of SLR within this century and over the next millennia will depend on the long-term temperature at which global warming will stabilize, as well as on the pathways

Table 1.

the IPCC AR6.²¹

the 17th-83rd percentile range. The

1900. Source:

Since the publication of the IPCC AR6 WGI in 2021, a growing number of scientific studies on ice-sheet loss are raising alarm among scientists that future SLR could indeed be much larger and occur sooner ²²

3. Global Impacts and Implications of Sea-Level Rise

Accelerated SLR has the potential to redefine the coastlines of the 21st century. It can pose major risks to the safety, security, and sustainability of many low-lying islands, populous coastal megacities, large tropical agricultural deltas, and Arctic communities.²⁷

The low-elevation coastal zone (LECZ), which comprises continental and island areas connected to the ocean at low elevation, includes a wide diversity of systems, from small islands to megacities, from the Tropics to the Poles, in both the Global North and Global South

Climate-driven coastal hazards and risks come not only from SLR itself but also from its amplification of storm surges, tides, and waves.

Small rises in relative sea-level can disproportionately increase coastal flooding frequency.³⁴ According to the United Nations Development Programme (UNDP) and the Climate =a dUM]@UVf]7=@žthe extent of coastal flooding has increased over the past 20 years as a result of SLR, meaning 14 million more people worldwide now live in coastal communities with a 1-in-20-year chance of flooding³⁵

The frequency of present-day, extreme-but-rare sea-level events is projected to increase substantially in most regions. For example, UWWfX]b['hc' h' Y=D77'5F*ž]b U['cVU' n]Uj YFU] YX' gYbgYžh Y%]b!%\$\$nYUF Yl fYa YgYU' Yj Y' Yj Ybi (in terms of total water level) is projected to occur cbWY' Yfmi' \$nYUfgVni&\$) S'UbXcbWY' Yfmi' nYUfg' Vni&\$) i bXYf' h' Y' FYdfYgYb]U]h] Y'7cbWb]fU]cb' DUh k UmF7D()' flb Ya]gg]cbg'gWbU]c' YUX]b['

communities to adapt to climate impacts through its destruction of natural coastal defenses and ecosystems. Mangroves, corals, saltmarshes, and seagrass meadows currently protect hundreds of millions of people worldwide against storm surges

a short timeline for adaptation implementation,

The IPCC AR6 has also highlighted that as sea levels rise and extreme events intensify, “coastal institutional, and socioeconomic constraints and

The Pacific SIDS are on the frontline of the climate crisis, facing severe and disproportionate impacts from SLR.

While the change in global-mean sea level from 1993 to 2023 was 9.4cm [+/- 1cm], sea level change in the South-West Pacific over the same period was greater than 15cm [+/- 3cm] in some locations.⁴² According to one recent study, most of the Pacific SIDS are located in a region where relative SLR is projected to be 10–30% higher than the global-mean SLR arising from Antarctic melt in 2100 relative to 2000.⁴⁴

Under a scenario of 3°C warming, which is roughly consistent with all locations across the Pacific region can expect to see at least another 15cm of additional SLR between 2020 and 2050 (Table 3). Between 2005 and 2100, the median SLR for the Pacific region ranges from 50–97cm across the five warming scenarios assessed, ranging from 1.5°C to 5°C. In many of the assessed locations, the projected SLR is significantly higher than the global-mean SLR.

Country	Tide Gauge Name	Observed SLR from
	Penrhyn	
	Rarotonga	
Fiji		
Fiji		
	Pohnpei	
Palau		
	Apia	
Tonga		
Tuvalu	Funafuti	

As also shown in Table 3, future SLR is projected to cause a large increase in the frequency and severity of episodic flooding in almost all locations in the Pacific SIDS in the coming decades. Across all future scenarios and under the assumption of no additional protections, all islands

for Nuku'alofa and Apia, the capital cities of Tonga and Samoa respectively, the number of flooding days will increase to 35 days per year during the 2050s for an average year. For a projected “worst year” of flooding the estimates increase to 70 and 90 days per year for Nuku'alofa and Apia, respectively. Under some locations in the Pacific SIDS could experience floodings for almost half of the entire year; for instance,

The Pacific SIDS, especially those in the western tropical Pacific (e.g., Kiribati, Tuvalu, and the Republic of the Marshall Islands), are particularly vulnerable to SLR because of: (i) high exposure to tropical cyclones and other tropical storms; (ii) high shoreline-to-land area ratios; (iii) high sensitivity to changes in sea level, waves, and currents; and (iv) its many low-lying coral atolls or volcanically-composed islands.

Many Pacific and other SIDS — home to 70 million people combined — are already experiencing loss of human life and significant economic damages, particularly from tropical cyclones and increases in SLR.⁵⁰ In the Solomon

5. Surging Seas in a Warming World: The Urgency of Action

the associated impacts and damages remain a complex challenge involving many geophysical and socioeconomic uncertainties, as our understanding of development and protection measures, **Nevertheless, one certainty that can be taken away from the latest research is that the climate crisis and SLR are no longer distant threats, especially for the Pacific SIDS.**

the national adaptation plan (NAP) process presents an opportunity for whole-of-economy comprehensive risk management, including actions to prepare for and manage the impacts of sea-level rise.

The outcome of the first global stocktake (GST) under the Paris Agreement

Deep, rapid, and sustained cuts in global greenhouse gas emissions are needed NOW to stay within a 1.5°C long-term warming trajectory. At the same time, effective coastal adaptation and investment in resilience and implementation must be scaled up worldwide, especially in the SIDS, to minimize growing SLR impacts and risks. For

Countries' next nationally determined contributions (NDCs) under the Paris Agreement, due in 2025, present an unprecedented opportunity for countries to rally cross-government and non-state actors to take immediate action to cut emissions, chart out 1.5°C-aligned decarbonization pathways, and build resilience to climate impacts. Similarly,
